

Protein & Nutrition Assessment

1 · Executive summary

Your current nutrition supports approximately 47% of your body's recovery requirements. The largest limiting factor appears to be protein intake. If maintained long term, this pattern may contribute to reduced muscle mass and slower recovery, lower energy stability, blunted recovery and afternoon energy dips. Small, consistent adjustments over the next 7–14 days produce the most visible change.

Nutrition snapshot

Protein		24/100
Carbohydrate quality		38/100
Fat quality		95/100
Hydration		60/100
Recovery support		35/100
OVERALL NUTRITION		49/100

Your daily targets

Calories: ~3163 kcal
Protein: 162–216 g
Carbohydrates: 316–435 g
Fat: 88–123 g
Hydration: ~3 L

2 · Muscle preservation

Current protein: 70 g/day
Recommended protein: 189 g/day
Status: High risk of gradual muscle loss without changes.

Muscle preservation score		34/100
---------------------------	------------------------	--------

After approximately age 35, adults naturally begin losing muscle mass unless resistance training and adequate protein intake are maintained.

3 · Protein strategy (omnivore)

Best protein sources for you:

- Eggs
- Greek yogurt
- Chicken breast
- Turkey
- Lean beef
- Fish (salmon, cod, tuna)
- Cottage cheese
- Whey protein

This assessment is educational and informational only. It is not a medical diagnosis and should not replace consultation with a qualified healthcare professional.

4 · Daily meal framework (~189 g protein)

Breakfast — 47 g protein

3 eggs + Greek yogurt + berries

Lunch — 57 g protein

Grilled chicken bowl, quinoa, vegetables, olive oil

Snack — 28 g protein

Cottage cheese + nuts, or a whey shake

Dinner — 57 g protein

Salmon or lean beef + sweet potato + greens

5 · Metabolic support

Metabolic support score

46/100

Biggest opportunities:

- Higher protein intake
- More muscle-building stimulus
- Better hydration

6 · Resistance training recommendation

Age: 47 Goal: fat_loss

- 3 resistance sessions per week
- 3 cardio sessions per week
- 10 minutes of daily mobility work

After approximately age 35, adults naturally lose muscle mass unless resistance training and adequate protein are maintained. Muscle preservation is one of the strongest predictors of healthy aging, mobility, and long-term metabolic health.

7 · Biological age impact factors

Positive:

- ' Healthy fat intake
- ' Sleep duration

Needs improvement:

- & Hydration
- & Protein intake
- & Recovery support
- & Alcohol load
- & Resistance training

Improving the items above may significantly improve energy, recovery, and long-term resilience. Educational estimate only.

Three highest-impact improvements

1. Anchor protein at breakfast

Aim for 30–40 g of protein within an hour of waking. Closes 30–50% of a daily protein gap on its own.

2. Add resistance training (3× per week)

Two to three short strength sessions per week is the single most underused longevity input.

3. Replace afternoon sugar snacks

Swap for a protein-forward option (yoghurt, eggs, cottage cheese, edamame). Stabilises afternoon energy.

8 · Isabella's weekly action plan

Your priority focus this week:

- & Reach 189 g of protein daily (currently ~70 g).
- & Add strength training 3× weekly.
- & Increase water intake to ~3 L per day.
- & Add vegetables to two meals daily.

Expected benefits:

- Improved satiety and fewer cravings
- Better recovery and energy stability
- Improved body composition over 4–8 weeks
- Stronger long-term metabolic and muscular foundation

7-day protein upgrade plan

- Day 1 — Protein breakfast (30–40 g). Hit hydration target.
- Day 2 — Add one vegetable-forward meal. Repeat protein breakfast.
- Day 3 — First strength session of the week (30–40 min).
- Day 4 — Front-load water (500 ml on waking + 500 ml mid-morning).
- Day 5 — Aim for protein at every meal (palm-sized portion).
- Day 6 — Second strength session + a zone-2 walk.
- Day 7 — Light review. Keep the two habits that felt easiest.
